# Overview of the package LMMstar

#### Brice Ozenne

## February 24, 2022

This vignette describes the main functionalities of the **LMMstar** package. This package implements specific types of linear mixed models mainly useful when having repeated observations over a discrete variable (e.g. time, brain region, ...). Key assumptions are that at the cluster level, observation are independent and identically distributed and that the mean and variance are independent (conditionally on covariates). In particular, in large samples the residuals do not have to be normally distributed.

### The LMMstar package contains four main functions:

- the function 1mm is the main function of the package which fits linear mixed models. The user can interact with *lmm* objects using:
  - anova to test linear combinations of coefficients (Wald test or Likelihood ratio tests). Can be combined via rbind.
  - coef to extract the estimates.
  - dummy.coef to extract the estimated (marginal) mean for each combination of categorical covariate.
  - estimate to test non-linear combinations of coefficients (Wald test via a first order delta method).
  - levels to extract the reference level for the mean structure. (i.e. what (Intercept) refers to in presence of categorical. covariates).
  - getVarCov to extract the modeled residual variance covariance matrix.
  - logLik to output the log-likelihood of the estimated model.
  - model.tables to extract table containing estimates with the corresponding uncertainty.
  - plot to obtain a diagnostic plots, partial residual plots, or a graphical display of the fitted values.
  - predict to compute the conditional mean for new observations.
  - residuals to extract the observed residuals of the fitted model.
  - summary to obtain a summary of the input, model fit, and estimated values.
- the summarize function to compute summary statistics stratified on a categorical variable (typically time).
- the sampleRem function to simulate longitudinal data.
- the LMMstar.options function enables the user to display the default values used in the LMMstar package. The function can also change the default values to better match the user needs.

Before going further we need to load the LMMstar package in the R session:

```
library(LMMstar)
```

To illustrate the functionalities of the package, we will use the gastricbypass dataset:

```
data(gastricbypassL, package = "LMMstar")
head(gastricbypassL)
```

```
time weight glucagon
  id visit
        1 3 months before surgery 127.2 5032.50
1
  1
        1 3 months before surgery 165.2 12142.50
2
3
 3
        1 3 months before surgery 109.7 10321.35
        1 3 months before surgery 146.2 6693.00
4
 4
        1 3 months before surgery 113.1 7090.50
  5
6 6
        1 3 months before surgery 158.8 10386.00
```

See ?gastricbypassL for a presentation of the database. We will use a shorter version of the time variable:

rescale the glucagon values

```
gastricbypassL$glucagon <- as.double(scale(gastricbypassL$glucagon))+5
```

and add a group variable:

```
gastricbypassL$group <- as.numeric(gastricbypassL$id)%%2</pre>
```

<u>Note:</u> the **LMMstar** package is under active development. Newer package versions may include additional functionalities and fix previous bugs. The version of the package that is being used is:

```
utils::packageVersion("LMMstar")
```

```
[1] '0.5.0'
```

When estimating model coefficients, we will use the internal optimization routine of the **LMMstar** package (instead of relying on the nlme::gls function, which is the default option):

```
LMMstar.options(optimizer = "FS")
```

# 1 Descriptive statistics

Mean, standard deviation, and other summary statistic can be computed with respect to a categorical variable (typically time) using the summarize function:

```
sss <- summarize(weight+glucagon \sim time, data = gastricbypassL, na.rm = TRUE) print(sss, digits = 3)
```

```
time observed missing
                                      mean
                                               sd

                                                    4.52
                                                           5.94
                                                                 8.27
8 glucagon A3_months
                                  0
                                      5.06 0.760
                                                    3.95
                                                           5.03
                                                                 7.12
                          20
```

Correlation matrices are also outure when a cluster and ordering variable have been specified (here respectively id and time):

```
sss <- summarize(weight \sim time|id, data = gastricbypassL, na.rm = TRUE) print(sss, digits = 3)
```

```
outcome
              time observed missing mean
                                           sd
                                               min median max

## 2.2 Model output

The summary method can be used to display the main information relative to the model fit:

```
summary(eUN.lmm)
```

Linear Mixed Model

Dataset: gastricbypassL

- 20 clusters
- 78 observations were analyzed, 2 were excluded because of missing values
- between 3 and 4 observations per cluster

Summary of the outcome and covariates:

```
$ weight : num 127 165 110 146 113 ...
$ time : Factor w/ 4 levels "B3_months", "B1_week", ..: 1 1 1 1 1 1 1 1 1 1 1 ...
$ glucagon: num  4.03 5.24 4.93 4.32 4.38 ...
reference level: time=B3_months
```

Estimation procedure

- Restricted Maximum Likelihood (REML)
- log-likelihood :-216.3189

glucagon
```

Uncertainty was quantified using model-based standard errors (column se).

Degrees of freedom were computed using a Satterthwaite approximation (column df).

The columns lower and upper indicate a 95% confidence interval for each coefficient.

<u>Note:</u> the calculation of the degrees of freedom, especially when using the observed information can be quite slow. Setting the arguments df to FALSE and type.information to "expected" when calling 1mm should lead to a more reasonnable computation time.

#### 2.3 Extract estimated coefficients

The value of the estimated coefficients can be output using coef:

```
coef(eUN.lmm)
```

```
(Intercept) timeB1_week timeA1_week timeA3_months glucagon 132.9801355 -7.8822331 -11.7879545 -26.1223908 -0.8883081
```

Variance coefficients can be output by specifying the effects argument:

```
coef(eUN.lmm, effects = "variance")
```

```
sigma k.B1_week k.A1_week k.A3_months 20.2808131 0.9390916 0.8705176 0.8264480
```

It is possible to apply specific transformation on the variance coefficients, for instance to obtain the residual variance relative to each outcome:

```
coef(eUN.lmm, effects = "variance", transform.k = "sd")
```

```
sigma:B3_months sigma:B1_week sigma:A1_week sigma:A3_months 20.28081 19.04554 17.65480 16.76104
```

The marginal means at each timepoint can be obtained using dummy.coef:

```
dummy.coef(eUN.lmm)
```

```
time estimate se df lower upper
1 B3_months 128.5386 4.536445 18.97584 119.04289 138.0343
2 B1_week 120.6564 4.261691 19.04078 111.73783 129.5749
3 A1_week 116.7506 3.956964 19.04925 108.47007 125.0312
4 A3_months 102.4162 3.747908 19.05531 94.57328 110.2591
```

## 2.4 Extract estimated coefficient and associated uncertainty

The uncertainty about the mean coefficients can be obtained using the model.tables method <sup>2</sup>:

```
model.tables(eUN.lmm)
```

```
estimate se df lower upper p.value (Intercept) 132.980 4.664 19.8 123.24 142.717 0.00e+00 timeB1_week -7.882 0.713 19.2 -9.37 -6.390 9.27e-10 timeA1_week -11.788 1.018 21.6 -13.90 -9.676 9.55e-11 timeA3_months -26.122 1.656 18.8 -29.59 -22.654 2.62e-12 glucagon -0.888 0.242 13.7 -1.41 -0.369 2.57e-03
```

Values for the all correlation parameters can be displayed too, by specifying effect="all":

```
model.tables(eUN.lmm, effect = "all") ## not shown
```

Because these parameters are constrained (e.g. strictly positive), they uncertainty is by default computed after transformation (e.g. log) and then backtransformed.

## 2.5 Extract estimated residual variance-covariance structure

The method getVarCov can be used to output the covariance structure of the residuals:

```
getVarCov(eUN.lmm)
```

```
B3_months B1_week A1_week A3_months
B3_months 411.3114 381.9734 352.6400 318.8573
B1_week 381.9734 362.7326 335.4649 304.6314
A1_week 352.6400 335.4649 311.6921 285.8077
A3_months 318.8573 304.6314 285.8077 280.9323
```

It can also be specific to a "known" individual:

```
getVarCov(eUN.lmm, individual = 5)
```

```
B3_months A1_week A3_months
B3_months 411.3114 352.6400 318.8573
A1_week 352.6400 311.6921 285.8077
A3_months 318.8573 285.8077 280.9323
```

or for a new individual:

```
newdata <- data.frame(id = "X", time = c("B3_months", "B1_week", "A1_week", "A3_months"))
getVarCov(eUN.lmm, individual = newdata)</pre>
```

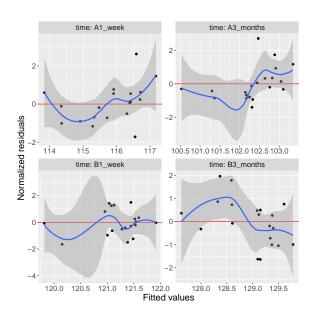

```
B3_months B1_week A1_week A3_months
B3_months 411.3114 381.9734 352.6400 318.8573
B1_week 381.9734 362.7326 335.4649 304.6314
A1_week 352.6400 335.4649 311.6921 285.8077
A3_months 318.8573 304.6314 285.8077 280.9323
```

<sup>&</sup>lt;sup>2</sup>it is equivalent to confint method except that by default it also outputs se and p.value

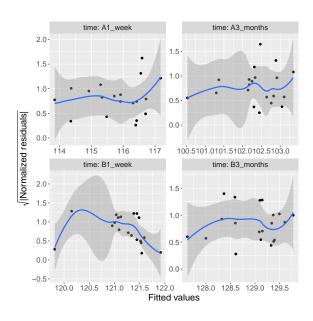

## 2.6 Model diagnostic

The method plot can be used to display diagnostic plots about:

• misspecification of the mean structure

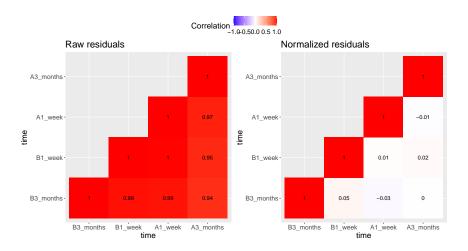

• misspecification of the variance structure

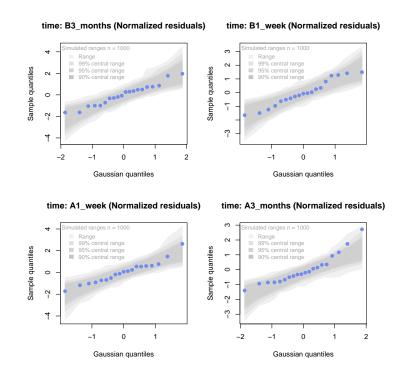

• misspecification of the correlation structure

```
plot(eUN.lmm, type = "correlation", type.residual = "response")
plot(eUN.lmm, type = "correlation", type.residual = "normalized")
```

• residual distribution vs. normal distribution <sup>3</sup>:

```
plot(eUN.lmm, type = "qqplot", engine.qqplot = "qqtest")
## Note: the qqtest package to be installed to use the argument engine.plot = "qqtest"
```

<sup>&</sup>lt;sup>3</sup>see Oldford (2016) for guidance about how to read quantile-quantile plots.

The method residuals returns the residulas in the wide format:

```
eUN.diagW <- residuals(eUN.lmm, type = "normalized", format = "wide")
colnames(eUN.diagW) <- gsub("normalized.","",colnames(eUN.diagW))
head(eUN.diagW)</pre>
```

```
cluster r.B3_months r.B1_week
                                  r.A1_week r.A3_months

          -0.2897365 -0.2027622 -1.16864038
                                               0.3258573
        2
2
            0.8603117 -1.6492164 0.62578801
                                               1.7370660
            0.7273066 -0.4155171 -0.68266741 -0.8510316
3
        3
4
         -1.6403082 -0.5128368 0.06806206
                                               1.1725813
5
        5
            0.4755409
                                             -0.8634200
                              NA -0.18736415
6
        6
            1.7801675 1.2847703 2.63004812
                                               0.3505542
```

or in the long format:

```
eUN.diagL <- residuals(eUN.lmm, type = "normalized", format = "long")
head(eUN.diagL)</pre>
```

```
[1] -0.2897365   0.8603117   0.7273066   -1.6403082   0.4755409   1.7801675
```

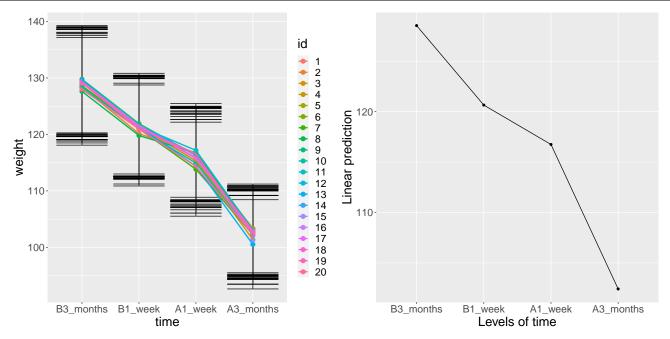

Various type of residuals can be extract but the normalized one are recommanded when doing model checking.

#### 2.7 Model fit

The fitted values can be displayed via the plot method or using the emmeans package:

```
library(ggplot2) ## left panel
plot(eUN.lmm, type = "fit", color = "id", ci.alpha = NA, size.text = 20)
```

```
library(emmeans) ## right panel
emmip(eUN.lmm, ~time) + theme(text = element_text(size=20))
```

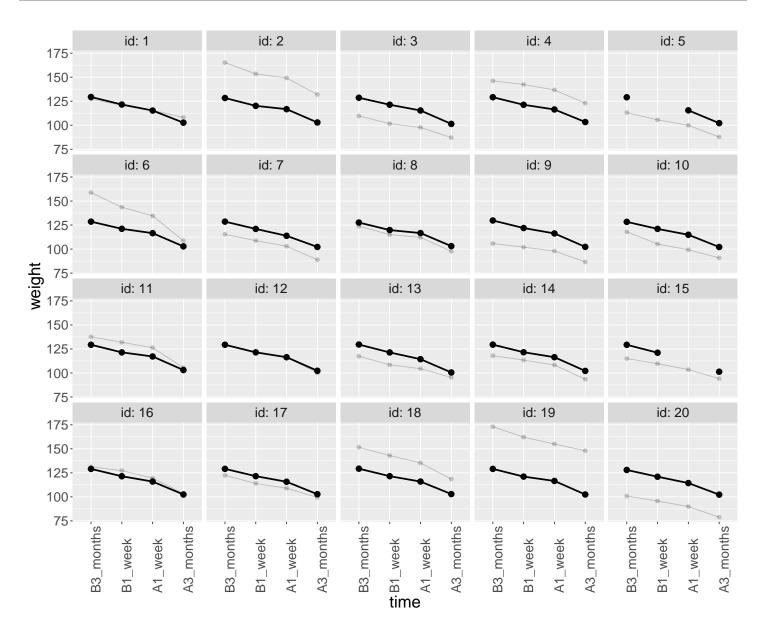

In the first case each possible curve is displayed while in the latter the average curve (over glucagon values). With the plot method, it is possible to display a curve specific to a glucagon value via the argument at:

```
plot(eUN.lmm, type = "fit", at = data.frame(glucagon = 10), color = "glucagon")
```

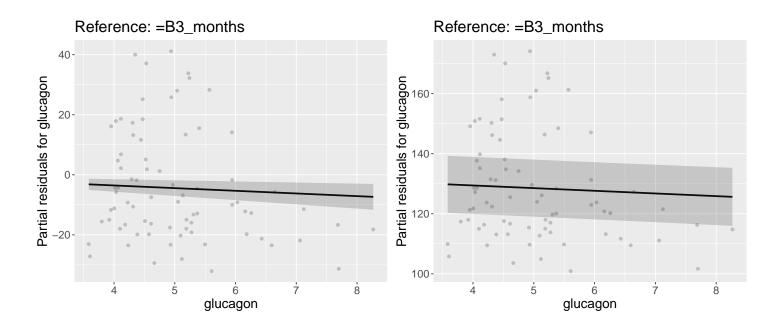

It is also possible to display the observed values along with the fitted values by setting the argument obs.alpha to a strictly positive value below or equal to 1. This argument controls the transparency of the color used to display the observed values:

```
gg <- plot(eUN.lmm, type = "fit", obs.alpha = 0.2, ci = FALSE,plot = FALSE)$plot
gg <- gg + facet_wrap(~id, labeller = label_both)
gg <- gg + theme(axis.text.x=element_text(angle = 90, hjust = 0))
gg</pre>
```

Partial residuals can also be displayed via the plot method:

```
gg1 <- plot(eUN.lmm, type = "partial", var = "glucagon", plot = FALSE)$plot
gg2 <- plot(eUN.lmm, type = "partial", var = c("(Intercept)", "glucagon"), plot = FALSE)$plot
ggarrange(gg1,gg2)</pre>
```

Their value can be extracted via the residuals method, e.g.:

```
df.pres <- residuals(eUN.lmm, type = "partial", var = "glucagon", keep.data = TRUE)
m.pres <- gastricbypassL$weight - model.matrix(~time,gastricbypassL) %*% coef(eUN.lmm)[1:4]
range(df.pres$r.partial - m.pres, na.rm = TRUE)</pre>
```

### [1] 4.44154 4.44154

## 2.8 Statistical inference (linear)

The anova method can be use to test one or several linear combinations of the model coefficients using Wald tests. By default, it will simultaneously test all parameters associated to a variable:

```
anova(eUN.lmm)
```

Note that here the p-values are not adjust for multiple comparisons over variables. It is possible to specify a null hypothesis to be test: e.g. is there a change in average weight just after taking the treatment:

```
anova(eUN.lmm, effects = c("timeA1_week-timeB1_week=0"))
```

```
| | User-specified linear hypotheses ||
- Multivariate Wald test (global null hypothesis)
statistic df.num df.denom    p.value
    43.141     1    17.875 3.7234e-06 ***
---
Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

One can also simulateneously tests several null hypotheses:

```
|| User-specified linear hypotheses ||
 - Multivariate Wald test (global null hypothesis)
 statistic df.num df.denom
                              p.value
    98.651
                    18.62 1.2338e-10 ***
                2
 - Univariate Wald test (individual null hypotheses)
                             estimate
                                                       df
                                                              lower
                                                                       upper p.value
                                             se
                                        0.59464 19.00000 -5.31234 -2.4991 < 1e-05 ***

Signif. codes: 0 '\*\*\* 0.001 '\*\* 0.01 '\* 0.05 '.' 0.1 ' 1 Standard errors: model-based (CIs/p-values adjusted for multiple comparisons -- single step max-test) or return all pairwise comparisons for a given factor using the mcp function of the multcomp package: library(multcomp) summary(anova(eUN.lmm, effects = mcp(time = "Tukey"))) Singular contrast matrix: contrasts "A1\_week - B1\_week" "A3\_months - B1\_week" "A3\_months - A1\_week" || User-specified linear hypotheses || - Multivariate Wald test (global null hypothesis) statistic df.num df.denom p.value 86.743 19.005 2.8424e-11 \*\*\* 3 - Univariate Wald test (individual null hypotheses) estimate se lower upper p.value B1\_week - B3\_months -7.88223 0.71318 20.00000 -9.79647 -5.9680 < 1e-05 \*\*\* A1\_week - B3\_months A3\_months - B3\_months -26.12239 1.65641 20.00000 -30.56833 -21.6764 < 1e-05 \*\*\* -3.90572 0.59464 20.00000 -5.50179 -2.3097 < 1e-05 \*\*\* A1\_week - B1\_week A3\_months - B1\_week -18.24016 1.32283 20.00000 -21.79075 -14.6896 < 1e-05 \*\*\* 1.05650 20.00000 -17.17018 -11.4987 < 1e-05 \*\*\* A3\_months - A1\_week -14.33444 Signif. codes: 0 '\*\*\* 0.001 '\*\* 0.01 '\* 0.05 '.' 0.1 ' ' 1 Standard errors: model-based (CIs/p-values adjusted for multiple comparisons -- single step max-test) Error when computing the adjusted p-value by numerical integration: 1.114e-06

When testing transformed variance or correlation parameters, parentheses (as in log(k).B1\_week) cause problem for recognizing parameters:

```
try(
    anova(eUN.lmm,
    effects = c("log(k).B1_week=0","log(k).A1_week=0","log(k).A3_months=0"))
)
```

```
Error in .anova_Wald(object, effects = effects, robust = robust, rhs = rhs, :
   Possible mispecification of the argument 'effects' as running mulcomp::glht lead to the following
Error in parse(text = ex[i]) : <text>:1:7: uventet symbol
1: log(k).B1_week
```

It is then advised to build a contrast matrix, e.g.:

```
name.coef <- rownames(confint(eUN.lmm, effects = "all"))
name.varcoef <- grep("^k",name.coef, value = TRUE)
C <- matrix(0, nrow = 3, ncol = length(name.coef), dimnames = list(name.varcoef, name.coef))
diag(C[name.varcoef,name.varcoef]) <- 1
C</pre>
```

```

k.B1_week
                                 0
                                                         0
                                                                                  0
k.A1_week
                                                                                  0
k.A3_months
                                 0
```

And then call the anova method specifying the null hypothesis via the contrast matrix:

```
anova(eUN.lmm, effects = C)
```

```
| | User-specified linear hypotheses ||
- Multivariate Wald test (global null hypothesis)
statistic df.num df.denom    p.value
    6.2032     3    17.995 0.0044171 **
---
Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

Note that using the approach of Pipper et al. (2012) it is also possible to adjust for multiple testing across several lmm objects. To do so, one first fit the mixed models, then use the anova method to indicate which hypotheses are being tested, and combine them using rbind.

Here is a (very artificial) example:

```
Manova <- rbind(anova(eInd.lmm, effects = "glucagon = 0"),
   anova(eCS.lmm, effects = "glucagon = 0"),
   anova(eUN.lmm, effects = "glucagon = 0"))
summary(Manova)</pre>
```

```
|| User-specified linear hypotheses ||
- Univariate Wald test (individual null hypotheses)
     estimate

```

## 2.9 Statistical inference (non-linear)

The estimate function can be used to test one or several non-linear combinations of model coefficients, using a first order delta method to quantify uncertainty. The combination has to be specified via a function (argument f). To illustrate its use consider an ANCOVA analysis:

$$Y_{i1} = \alpha + \beta Y_{i,0} + \gamma X_i + e_i$$

```
Estimate Std. Error t value Pr(>|t|)

(Intercept) -1.4823022 2.31781138 -0.6395267 5.310047e-01

weight.B1_week 0.9654917 0.01803988 53.5198489 2.156258e-20

group 0.2521714 0.66499945 0.3792054 7.092302e-01
```

We can replicate this analysis by first fitting a mixed model:

$$Y_{ij} = \alpha_j + \gamma_j X_i + \varepsilon_{i,j} \text{ where } \varepsilon_i \sim \mathcal{N}\left(\begin{bmatrix} 0\\0 \end{bmatrix}, \begin{bmatrix} \sigma_1^2 & \rho\sigma_1\sigma_2\\ \rho\sigma_1\sigma_2 & \sigma_2^2 \end{bmatrix}\right)$$

```
e.lmmANCOVA <- lmm(weight \sim time+time:group, repetition = \simtime|id, data = gastricbypassL[gastricbypassL$visit %in% 2:3,])
```

and then perform a delta-method:

```
lava::estimate(e.lmmANCOVA, f = function(p){
    c(Y1 = as.double(p["rho(B1_week,A1_week)"]*p["k.A1_week"]),
        X1 = as.double(p["timeA1_week:group"]-p["rho(B1_week,A1_week)"]*p["k.A1_week"]*p["timeB1_week:group"]))
})
```

```
estimate se df lower upper p.value
Y1 0.9654917 0.01753161 15.96769 0.9283203 1.002663 0.0000000
X1 0.2521714 0.64626331 15.00349 -1.1252784 1.629621 0.7018731
```

Indeed:

$$\mathbb{E}\left[Y_{i2}|Y_{i1}, X_i\right] = \alpha_2 + \gamma_2 X_i + \rho \frac{\sigma_2}{\sigma_1} \left(Y_{i1} - \alpha_1 - \gamma_1 X_i\right)$$
$$= \alpha_2 - \rho \frac{\sigma_2}{\sigma_1} \alpha_1 + \rho \frac{\sigma_2}{\sigma_1} Y_{i1} + \left(\gamma_2 - \rho \frac{\sigma_2}{\sigma_1} \gamma_1\right) X_i$$

We obtain identical estimate but different standard-errors/degrees of freedom compared to the univariate linear model approach. The later is to be prefer as it does not rely on approximation. The former is nevertheless useful as it can handle missing data in the outcome variable.

## 2.10 Baseline adjustment

The 1mm contains an "experimental" feature to drop non-identifiable effects from the model. For instance, let us define two (artifical) groups of patients:

```
gastricbypassL$group <- c("1","2")[as.numeric(gastricbypassL$id) %in% 15:20 + 1]
```

We would like to model group differences only after baseline (i.e. only at 1 week and 3 months after). For this we will define a treatment variable being the group variable except before baseline where it is "none":

```
, , group = 1
treat B3_months B1_week A1_week A3_months
 none
               14
                       14
                                 0
                                            0
                0
                        0
                                14
                                           14
  1
                0
  2
                        0
                                 0
                                            0
 , group = 2
      time
treat B3_months B1_week A1_week A3_months
 none
                6
                        6
                                 0
                        0
                                 0
                                            0
  1
  2
                        0
                                 6
                                            6
```

Here we will be able to estimate a total of 6 means and therefore can at most identify 6 effects. However the design matrix for the interaction model:

```
colnames(model.matrix(weight \sim treat*time, data = gastricbypassL))
```

```
[1] "(Intercept)" "treat1" "treat2" "timeB1_week"
[5] "timeA1_week" "timeA3_months" "treat1:timeB1_week" "treat2:timeB1_week"
[9] "treat1:timeA1_week" "treat2:timeA1_week" "treat2:timeA3_months"
```

contains 12 parameters (i.e. 6 too many). The 1mm function will internally remove the one that cannot be identified and fit a simplified model:

```
eC.lmm <- lmm(weight \sim treat*time, data = gastricbypassL, repetition = \simtime|id, structure = "UN")
```

```
Constant values in the design matrix in interactions "treat:time"

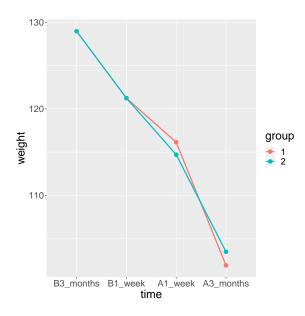

Coefficients "treat1" "treat2" "timeA1_week" "timeA3_months" "treat1:timeB1_week" "treat2:timeB1_w
```

with the following coefficients:

```
coef(eC.lmm, effects = "mean")
```

One can vizualize the baseline adjustment via the autoplot function:

```
autoplot(eC.lmm, color = "group", ci = FALSE, size.text = 20)
```

To more easily compare the two groups, one could set the baseline treatment to the treatment in the control arm by omitting the argument new.level:

```
, group = 1
     time
treat B3_months B1_week A1_week A3_months
             14
                     14
                            14
                                        14
    2
              0
                     0
                              0
                                        0
 , group = 2
treat B3_months B1_week A1_week A3_months
    1
              6
                      6
                              0
              0
    2
                      0
                              6
                                        6
```

```
eC2.lmm <- suppressWarnings(lmm(weight \sim treat2*time, data = gastricbypassL, repetition = \simtime|id, structure = "UN"))
```

Constant values in the design matrix in interactions "treat2:time" Coefficients "treat22" "treat22:timeB1\_week" have been removed.

will directly output group differences (last two coefficients):

```
model.tables(eC2.lmm)
```

```
      (Intercept)
      128.97
      4.532
      19.0
      119.48
      138.46
      0.00e+00

      timeB1_week
      -7.73
      0.697
      19.0
      -9.19
      -6.27
      1.00e-09

## 2.11 Marginal means

The emmeans package can be used to output marginal means. Consider the following model:

```
e.group <- lmm(weight \sim time*group, data = gastricbypassL, repetition = \simtime|id, structure = "UN")
```

We can for instance compute the average value over time assuming balanced groups:

```
emmeans(e.group, specs=~time)
```

```
NOTE: Results may be misleading due to involvement in interactions
                       df lower.CL upper.CL
           emmean
                   SE
B3_months
             130 5.05 18.0
                               119.3
B1_week
             122 4.69 18.0
                               112.5
                                          132
              117 4.55 18.0
                               107.0
                                          126
 A1_{week}
             104 4.20 18.1
                               94.9
 A3_months
                                          113
```

Results are averaged over the levels of: group Confidence level used: 0.95

This differs from the average value over time over the whole sample:

```
df.pred <- cbind(gastricbypassL, predict(e.group, newdata = gastricbypassL))
summarize(formula = estimate~time, data = df.pred)</pre>
```

```
time observed missing
   outcome
                                                    sd
                                                            min
                                                                  median
                                         mean
                                    0 128.970 2.270212 127.5214 127.5214 132.35
1 estimate B3_months
                           20

                                    0 115.700 2.014981 114.4143 114.4143 118.70
3 estimate
            A1_week
                           20
                                    0 102.365 3.146729 100.3571 100.3571 107.05
4 estimate A3_months
                           20
```

as the groups are not balanced:

```
table(group = gastricbypassL$group, time = gastricbypassL$time)
```

```
time
group B3_months B1_week A1_week A3_months
1 14 14 14 14 14
2 6 6 6 6
```

The "emmeans" approach gives equal "weight" to the expected value of both group 2:

```
emmeans predict 129.9357 128.9700
```

Which one is relevant depends on the application. The emmeans function can also be used to display expected value in each group over time:

```
emmeans.group <- emmeans(e.group, specs = \simgroup|time) emmeans.group
```

```
time = B3_months:
 group emmean
                SE
                     df lower.CL upper.CL

                                      122
```

Confidence level used: 0.95

Using the pair function displays the differences:

```
epairs.group <- pairs(emmeans.group, reverse = TRUE)
epairs.group</pre>
```

```
time = B3_months:
contrast estimate
                   SE
                        df t.ratio p.value
2 - 1 4.83 10.10 18.0 0.478 0.6383
time = B1_week:
contrast estimate
                   SE
                        df t.ratio p.value
            5.80 9.38 18.0 0.618 0.5441
time = A1_week:
contrast estimate
                  SE df t.ratio p.value
2 - 1
            4.29 9.11 18.0 0.471 0.6435
time = A3_months:

P value adjustment: sidak method for 4 tests

#### 2.12 Predictions

Two types of predictions can be performed with the predict method:

• static predictions that are only conditional on the covariates:

```
news <- gastricbypassL[gastricbypassL$id==1,]
news$glucagon <- 0
predict(eUN.lmm, newdata = news)</pre>
```

```
estimate se df lower upper
1 132.9801 4.664247 19.75815 123.24305 142.7172
2 125.0979 4.388294 19.91418 115.94155 134.2543
3 121.1922 4.214230 20.55331 112.41660 129.9678
4 106.8577 3.942058 20.95499 98.65871 115.0568
```

which can be computing by creating a design matrix:

```
X.12 <- model.matrix(formula(eUN.lmm), news)
X.12</pre>
```

```
(Intercept) timeB1_week timeA1_week timeA3_months glucagon

              1
                           1
                                        0
                                                        0
                                                                  0
41
                           0
                                                        0
                                                                  0
              1
                                        1
              1
                           0
                                        0
                                                                  0
61
                                                        1
attr(, "assign")
[1] 0 1 1 1 2
attr(,"contrasts")
attr(,"contrasts")$time
[1] "contr.treatment"
```

and then multiplying it with the regression coefficients:

```
X.12 %*% coef(eUN.lmm)
```

```
[,1]
1 132.9801
21 125.0979
41 121.1922
61 106.8577
```

• dynamic predictions that are conditional on the covariates and the outcome measured at other timepoints. Consider two subjects for who we would like to predict the weight 1 week before the intervention based on the weight 3 months before the intervention:

```
newd <- rbind(
  data.frame(id = 1, time = "B3_months", weight = coef(eUN.lmm)["(Intercept)"], glucagon = 0),
  data.frame(id = 1, time = "B1_week", weight = NA, glucagon = 0),
  data.frame(id = 2, time = "B3_months", weight = 100, glucagon = 0),
  data.frame(id = 2, time = "B1_week", weight = NA, glucagon = 0)
)
predict(eUN.lmm, newdata = newd, type = "dynamic", keep.newdata = TRUE)</pre>
```

```
weight glucagon
  id
          time
                                   estimate
                                                    se
                                                        df
                                                                lower
                                                                         upper
   1 B3 months 132.9801
1
                                                        NA
                                                                   NA
                                         NA

                                                                   NA
                                                                            NA
       B1 week
                                0 94.47017 7.2279385 Inf
                                                           80.30367 108.6367
                      NA
```

The first subjects has the average weight while the second has a much lower weight. The predicted weight for the first subject is then the average weight one week before while it is lower for the second subject due to the positive correlation over time. The predicted value is computed using the formula of the conditional mean for a Gaussian vector:

```
mu1 <- coef(eUN.lmm)[1]
mu2 <- sum(coef(eUN.lmm)[1:2])
Omega_11 <- getVarCov(eUN.lmm)["B3_months","B3_months"]
Omega_21 <- getVarCov(eUN.lmm)["B1_week","B3_months"]
as.double(mu2 + Omega_21 * (100 - mu1) / Omega_11)</pre>
```

[1] 94.47017

## 2.13 Missing values and imputation

We now consider the glucagon level as an outcome. The **summarize** function can be used to describe the amount of missing data at each repetition:

```
sss <- summarize(glucagon \sim time, data = gastricbypassL, na.rm = TRUE) cbind(sss[,1:4], pc = paste0(100 * sss$missing / (sss$missing + sss$observed), "%"))
```

```
time observed missing pc
   outcome
1 glucagon B3_months
                           20
                                     0 0%
2 glucagon
             B1_week
                           19
                                     1 5%
3 glucagon
             A1_week
                           19
                                     1 5%
4 glucagon A3_months
                           20
                                     0 0%
```

Further description of the missing data patterns rely on function outside the LMMstar package, e.g. appropriate call to tapply and table:

```
vec.pattern
0.0.0.0 0.0.1.0 0.1.0.0
18 1 1
```

Linear mixed model can handle missing value in the outcome variable, assuming that missigness is random conditional on the covariate and observed outcome values. The 1mm function can be used "as usual":

```
eUN.lmmNA <- lmm(glucagon ~ time,
    repetition = ~time|id, structure = "UN",
    data = gastricbypassL)
summary(eUN.lmmNA, hide.fit = TRUE,
    hide.cor = TRUE, hide.sd = TRUE, hide.mean = TRUE)</pre>
```

Linear Mixed Model

Dataset: gastricbypassL

- 20 clusters
- 78 observations were analyzed, 2 were excluded because of missing values
- between 3 and 4 observations per cluster

Summary of the outcome and covariates:

```
$ glucagon: num 4.03 5.24 4.93 4.32 4.38 ...
$ time : Factor w/ 4 levels "B3_months", "B1_week", ..: 1 1 1 1 1 1 1 1 1 1 1 ...
reference level: time=B3_months
```

The visible difference in the summary is when describing the dataset: we can see that some repetitions (here 2) have been ignored as the outcome was missing. So for some clusters only 3 values were analyzed instead of 4. It is possible to extract the most likely value for these missing observation using the fitted function with argument impute=TRUE:

```
fitted(eUN.lmmNA, impute = TRUE)
```

#### [1] 4.256984 6.497856

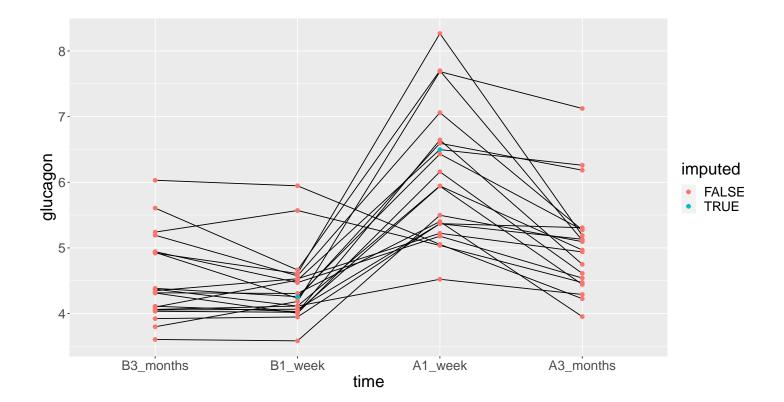

When using the argument keep.newdata=TRUE, the missing outcome value has been replaced by its most likely value (which is the same as the dynamic prediction, describedy previously):

```
eData <- fitted(eUN.lmmNA, impute = TRUE, keep.newdata = TRUE)
eData[eData$id %in% eData[eData$imputed,"id"],]
```

```

                                                                         FALSE 5.057642
75 15
                         94.1 6.259632
                                            FALSE
```

#### Visually:

```
ggplot(eData, aes(x=time,y=glucagon, group=id)) + geom_line() + geom_point(aes(color=imputed))
```

It is possible to sample from the estimated distribution of the missing value instead of using the most likely value, e.g. accounting for residual variance and uncertainty related to parameter estimation:

```
set.seed(10)
fitted(eUN.lmmNA, impute = TRUE, se = "total")
fitted(eUN.lmmNA, impute = TRUE, se = "total")
fitted(eUN.lmmNA, impute = TRUE, se = "total")
```

[1] 4.262434 6.305287 [1] 3.858267 5.871642 [1] 4.342624 6.905246

# 4 Modifying default options

The LMMstar.options method enable to get and set the default options used by the package. For instance, the default option for the information matrix is:

LMMstar.options("type.information")

\$type.information
[1] "observed"

To change the default option to "expected" (faster to compute but less accurate p-values and confidence intervals in small samples) use:

LMMstar.options(type.information = "expected")

To restore the original default options do:

LMMstar.options(reinitialise = TRUE)

## 5 R session

## Appendix A Likelihood in a linear mixed model

Denote by Y a vector of m outcomes, X a vector of p covariates,  $\mu(\Theta, X)$  the modeled mean, and  $\Omega(\Theta, X)$  the modeled residual variance-covariance. We consider n replicates (i.e.  $Y_1, \ldots, Y_n$ ) and  $VX_1, \ldots, X_n$ ) along with a vector of weights  $\omega = (w_1, \ldots, w_n)$ , which are by default all equal to 1.

## A.1 Log-likelihood

The restricted log-likelihood in a linear mixed model can then be written:

$$\mathcal{L}(\boldsymbol{\Theta}|\boldsymbol{Y},\boldsymbol{X}) = \frac{p}{2}\log(2\pi) - \frac{1}{2}\log\left(\left|\sum_{i=1}^{n} w_{i}\boldsymbol{X}_{i}\Omega_{i}^{-1}(\boldsymbol{\Theta})\boldsymbol{X}_{i}^{\mathsf{T}}\right|\right) + \sum_{i=1}^{n} w_{i}\left(-\frac{m}{2}\log(2\pi) - \frac{1}{2}\log|\Omega_{i}(\boldsymbol{\Theta})| - \frac{1}{2}(\boldsymbol{Y}_{i} - \mu(\boldsymbol{\Theta},\boldsymbol{X}_{i}))\Omega_{i}(\boldsymbol{\Theta})^{-1}(\boldsymbol{Y}_{i} - \mu(\boldsymbol{\Theta},\boldsymbol{X}_{i}))^{\mathsf{T}}\right)$$
(A)

This is what the logLik method is computing for the REML criteria. The red term is specific to the REML criteria and prevents from computing individual contributions to the likelihood<sup>4</sup>. The blue term is what logLik outputs for the ML criteria when setting the argument indiv to TRUE.

#### A.2 Score

Using that  $\partial \log(\det(X)) = tr(X^{-1}\partial(X))$ , the score is obtained by derivating once the log-likelihood, i.e., for  $\theta \in \Theta$ :

$$S(\theta) = \frac{\partial \mathcal{L}(\boldsymbol{\Theta}|\boldsymbol{Y}, \boldsymbol{X})}{\partial \theta} = \frac{1}{2} tr \left( \left( \sum_{i=1}^{n} w_{i} \boldsymbol{X}_{i} \Omega_{i}^{-1}(\boldsymbol{\Theta}) \boldsymbol{X}_{i}^{\mathsf{T}} \right)^{-1} \left( \sum_{i=1}^{n} w_{i} \boldsymbol{X}_{i} \Omega_{i}^{-1}(\boldsymbol{\Theta}) \frac{\partial \Omega_{i}(\boldsymbol{\Theta})}{\partial \theta} \Omega_{i}(\boldsymbol{\Theta})^{-1} \boldsymbol{X}_{i}^{\mathsf{T}} \right) \right)$$

$$+ \sum_{i=1}^{n} w_{i} \left( -\frac{1}{2} tr \left( \Omega_{i}(\boldsymbol{\Theta})^{-1} \frac{\partial \Omega_{i}(\boldsymbol{\Theta})}{\partial \theta} \right) + \frac{\partial \mu(\boldsymbol{\Theta}, \boldsymbol{X}_{i})}{\partial \theta} \Omega_{i}(\boldsymbol{\Theta})^{-1} (\boldsymbol{Y}_{i} - \mu(\boldsymbol{\Theta}, \boldsymbol{X}_{i}))^{\mathsf{T}} \right)$$

$$+ \frac{1}{2} (\boldsymbol{Y}_{i} - \mu(\boldsymbol{\Theta}, \boldsymbol{X}_{i})) \Omega_{i}(\boldsymbol{\Theta})^{-1} \frac{\partial \Omega_{i}(\boldsymbol{\Theta})}{\partial \theta} \Omega_{i}(\boldsymbol{\Theta})^{-1} (\boldsymbol{Y}_{i} - \mu(\boldsymbol{\Theta}, \boldsymbol{X}_{i}))^{\mathsf{T}} \right).$$

This is what the **score** method is computing for the REML criteria. The red term is specific to the REML criteria and prevents from computing the score relative to each cluster. The blue term is what **score** outputs for the ML criteria when setting the argument **indiv** to TRUE.

<sup>&</sup>lt;sup>4</sup>The REML is the likelihood of the observations divided by the prior on the estimated mean parameters  $\widehat{\Theta}_{\mu} \sim \mathcal{N}(\mu, (\boldsymbol{X}\Omega^{-1}(\boldsymbol{\Theta})\boldsymbol{X}^{\intercal})^{-1})$ . This corresponds to  $\frac{1}{\sqrt{2\pi^{p}}\left|\left(\sum_{i=1}^{n}\boldsymbol{X}_{i}\Omega_{i}^{-1}(\boldsymbol{\Theta})\boldsymbol{X}_{i}^{\intercal}\right)^{-1}\right|} \exp\left(-(\widehat{\Theta}_{\mu}-\mu)\left(2\sum_{i=1}^{n}\boldsymbol{X}_{i}\Omega_{i}^{-1}(\boldsymbol{\Theta})\boldsymbol{X}_{i}^{\intercal}\right)^{-1}\right)(\widehat{\Theta}_{\mu}-\mu)^{\intercal}\right) \text{ Since } \mu \text{ will be estimated to be } \widehat{\Theta}_{\mu}, \text{ the exponential term equals 1 and thus does not contribute to the log-likelihood. One divided by the other term gives <math display="block">\sqrt{2\pi^{p}}\left(\left|\sum_{i=1}^{n}\boldsymbol{X}_{i}\Omega_{i}^{-1}(\boldsymbol{\Theta})\boldsymbol{X}_{i}^{\intercal}\right|\right)^{-1}. \text{ The log of this term equals the red term}$ 

### A.3 Hessian

Derivating a second time the log-likelihood gives the hessian,  $\mathcal{H}(\Theta)$ , with element<sup>5</sup>:

$$\begin{split} \mathcal{H}(\theta,\theta') &= \frac{\partial^{2}\mathcal{L}(\boldsymbol{\Theta}|\boldsymbol{Y},\boldsymbol{X})}{\partial\theta\partial\theta'} = \frac{\partial\mathcal{S}(\theta)}{\partial\theta'} \\ &= \frac{1}{2}tr\left(\left(\sum_{i=1}^{n}w_{i}\boldsymbol{X}_{i}\Omega_{i}^{-1}(\boldsymbol{\Theta})\boldsymbol{X}_{i}^{\intercal}\right)^{-1}\left\{\sum_{i=1}^{n}w_{i}\boldsymbol{X}_{i}\Omega_{i}^{-1}(\boldsymbol{\Theta})\left(\frac{\partial^{2}\Omega_{i}(\boldsymbol{\Theta})}{\partial\theta\partial\theta'} - 2\frac{\partial\Omega_{i}(\boldsymbol{\Theta})}{\partial\theta}\Omega_{i}^{-1}(\boldsymbol{\Theta})\frac{\partial\Omega_{i}(\boldsymbol{\Theta})}{\partial\theta'}\right)\Omega_{i}(\boldsymbol{\Theta})^{-1}\boldsymbol{X}_{i}^{\intercal}\right) \\ &+ \left(\sum_{i=1}^{n}w_{i}\boldsymbol{X}_{i}\Omega_{i}^{-1}(\boldsymbol{\Theta})\frac{\partial\Omega_{i}(\boldsymbol{\Theta})}{\partial\theta}\Omega_{i}(\boldsymbol{\Theta})^{-1}\boldsymbol{X}_{i}^{\intercal}\right)\left(\sum_{i=1}^{n}w_{i}\boldsymbol{X}_{i}\Omega_{i}^{-1}(\boldsymbol{\Theta})\boldsymbol{X}_{i}^{\intercal}\right)^{-1}\left(\sum_{i=1}^{n}w_{i}\boldsymbol{X}_{i}\Omega_{i}^{-1}(\boldsymbol{\Theta})\frac{\partial\Omega_{i}(\boldsymbol{\Theta})}{\partial\theta'}\Omega_{i}(\boldsymbol{\Theta})^{-1}\boldsymbol{X}_{i}^{\intercal}\right)\right\} \\ &+ \sum_{i=1}^{n}w_{i}\left(\frac{1}{2}tr\left(\Omega_{i}(\boldsymbol{\Theta})^{-1}\frac{\partial\Omega_{i}(\boldsymbol{\Theta})}{\partial\theta'}\Omega_{i}(\boldsymbol{\Theta})^{-1}\frac{\partial\Omega_{i}(\boldsymbol{\Theta})}{\partial\theta} - \Omega_{i}(\boldsymbol{\Theta})^{-1}\frac{\partial^{2}\Omega_{i}(\boldsymbol{\Theta})}{\partial\theta\partial\theta'}\right) \\ &- \frac{\partial\mu(\boldsymbol{\Theta},\boldsymbol{X}_{i})}{\partial\theta}\Omega_{i}(\boldsymbol{\Theta})^{-1}\frac{\partial\Omega_{i}(\boldsymbol{\Theta})}{\partial\theta'}\Omega_{i}(\boldsymbol{\Theta})^{-1}\varepsilon_{i}(\boldsymbol{\Theta})^{\intercal} - \frac{\partial\mu(\boldsymbol{\Theta},\boldsymbol{X}_{i})}{\partial\theta}\Omega_{i}(\boldsymbol{\Theta})^{-1}\frac{\partial\mu(\boldsymbol{\Theta},\boldsymbol{X}_{i})}{\partial\theta'} \\ &+ \frac{1}{2}\varepsilon_{i}(\boldsymbol{\Theta})\Omega_{i}(\boldsymbol{\Theta})^{-1}\left(\frac{\partial^{2}\Omega_{i}(\boldsymbol{\Theta})}{\partial\theta\partial\theta'} - \frac{\partial\Omega_{i}(\boldsymbol{\Theta})}{\partial\theta'}\Omega_{i}(\boldsymbol{\Theta})^{-1}\frac{\partial\Omega_{i}(\boldsymbol{\Theta})}{\partial\theta'}\Omega_{i}(\boldsymbol{\Theta})^{-1}\frac{\partial\Omega_{i}(\boldsymbol{\Theta})}{\partial\theta'}\Omega_{i}(\boldsymbol{\Theta})^{-1}\frac{\partial\Omega_{i}(\boldsymbol{\Theta})}{\partial\theta'}\Omega_{i}(\boldsymbol{\Theta})^{-1}\frac{\partial\Omega_{i}(\boldsymbol{\Theta})}{\partial\theta'}\Omega_{i}(\boldsymbol{\Theta})^{-1}\varepsilon_{i}(\boldsymbol{\Theta})^{\intercal}\right). \end{split}$$

where  $\boldsymbol{\varepsilon}_i(\boldsymbol{\Theta}) = \boldsymbol{Y}_i - \mu(\boldsymbol{\Theta}, \boldsymbol{X}_i)$ .

The information method will (by default) return the (observed) information which is the opposite of the hessian. So multiplying the previous formula by -1 gives what information output for the REML criteria. The red term is specific to the REML criteria and prevents from computing the information relative to each cluster. The blue term is what information outputs for the ML criteria (up to a factor -1) when setting the argument indiv to TRUE.

A possible simplification is to use the expected hessian at the maximum likelihood. Indeed for any deterministic matrix A:

• 
$$\mathbb{E}\left[A(\boldsymbol{Y}_i - \mu(\boldsymbol{\Theta}, \boldsymbol{X}_i))^{\mathsf{T}} | \boldsymbol{X}_i\right] = 0$$

• 
$$\mathbb{E}\left[(\boldsymbol{Y}_i - \mu(\boldsymbol{\Theta}, \boldsymbol{X}_i))A(\boldsymbol{Y}_i - \mu(\boldsymbol{\Theta}, \boldsymbol{X}_i))^{\mathsf{T}}||\boldsymbol{X}_i\right] = tr(A\mathbb{V}ar(\boldsymbol{Y}_i - \mu(\boldsymbol{\Theta}, \boldsymbol{X}_i)))$$

when  $\mathbb{E}[\boldsymbol{Y}_i - \mu(\boldsymbol{\Theta}, \boldsymbol{X}_i)] = 0$ . This leads to:

 $\mathbb{E}\left[\mathcal{H}(\theta, \theta') | \boldsymbol{X}\right]$ 

$$= \frac{1}{2} tr \left( \left( \sum_{i=1}^{n} w_{i} \boldsymbol{X}_{i} \Omega_{i}^{-1}(\boldsymbol{\Theta}) \boldsymbol{X}_{i}^{\mathsf{T}} \right)^{-1} \left\{ \sum_{i=1}^{n} w_{i} \boldsymbol{X}_{i} \Omega_{i}^{-1}(\boldsymbol{\Theta}) \left( \frac{\partial^{2} \Omega_{i}(\boldsymbol{\Theta})}{\partial \theta \partial \theta'} - 2 \frac{\partial \Omega_{i}(\boldsymbol{\Theta})}{\partial \theta} \Omega_{i}^{-1}(\boldsymbol{\Theta}) \frac{\partial \Omega_{i}(\boldsymbol{\Theta})}{\partial \theta'} \right) \Omega_{i}(\boldsymbol{\Theta})^{-1} \boldsymbol{X}_{i}^{\mathsf{T}} \right\} + \left( \sum_{i=1}^{n} w_{i} \boldsymbol{X}_{i} \Omega_{i}^{-1}(\boldsymbol{\Theta}) \frac{\partial \Omega_{i}(\boldsymbol{\Theta})}{\partial \theta} \Omega_{i}(\boldsymbol{\Theta})^{-1} \boldsymbol{X}_{i}^{\mathsf{T}} \right) \left( \sum_{i=1}^{n} w_{i} \boldsymbol{X}_{i} \Omega_{i}^{-1}(\boldsymbol{\Theta}) \boldsymbol{X}_{i}^{\mathsf{T}} \right)^{-1} \left( \sum_{i=1}^{n} w_{i} \boldsymbol{X}_{i} \Omega_{i}^{-1}(\boldsymbol{\Theta}) \frac{\partial \Omega_{i}(\boldsymbol{\Theta})}{\partial \theta'} \Omega_{i}(\boldsymbol{\Theta})^{-1} \boldsymbol{X}_{i}^{\mathsf{T}} \right) \right\} \right) + \sum_{i=1}^{n} w_{i} \left( -\frac{1}{2} tr \left( \Omega_{i}(\boldsymbol{\Theta})^{-1} \frac{\partial \Omega_{i}(\boldsymbol{\Theta})}{\partial \theta'} \Omega_{i}(\boldsymbol{\Theta})^{-1} \frac{\partial \Omega_{i}(\boldsymbol{\Theta})}{\partial \theta} \right) - \frac{\partial \mu(\boldsymbol{\Theta}, \boldsymbol{X}_{i})}{\partial \theta} \Omega_{i}(\boldsymbol{\Theta})^{-1} \frac{\partial \mu(\boldsymbol{\Theta}, \boldsymbol{X}_{i})}{\partial \theta'} \right) \right)$$
(B)

This is what information output when the argument type.information is set to "expected" (up to a factor -1).

<sup>&</sup>lt;sup>5</sup>if one is relative to the mean and the other to the variance then they are respectively  $\theta$  and  $\theta'$ 

## A.4 Degrees of freedom

Degrees of freedom are computed using a Satterthwaite approximation, i.e. for an estimate coefficient  $\widehat{\beta} \in \widehat{\Theta}$  with standard error  $\sigma_{\widehat{beta}}$ , the degree of freedom is:

$$df\left(\sigma_{\widehat{\beta}}\right) = \frac{2\sigma_{\widehat{\beta}}^4}{\mathbb{V}ar\left[\widehat{\sigma}_{\widehat{\beta}}\right]}$$

Using a first order Taylor expansion we can approximate the variance term as:

$$Var\left[\widehat{\sigma}_{\widehat{\beta}}\right] \approx \frac{\partial \widehat{\sigma}_{\widehat{\beta}}}{\partial \mathbf{\Theta}} \Sigma_{\mathbf{\Theta}} \frac{\partial \widehat{\sigma}_{\widehat{\beta}}}{\partial \mathbf{\Theta}}^{\mathsf{T}}$$

$$\approx c_{\beta} \left(\widehat{\mathcal{I}}_{\widehat{\mathbf{\Theta}}}\right)^{-1} \frac{\partial \widehat{\mathcal{I}}_{\widehat{\mathbf{\Theta}}}}{\partial \mathbf{\Theta}} \left(\widehat{\mathcal{I}}_{\widehat{\mathbf{\Theta}}}\right)^{-1} c_{\beta}^{\mathsf{T}} \Sigma_{\mathbf{\Theta}} c_{\beta}^{\mathsf{T}} \left(\widehat{\mathcal{I}}_{\widehat{\mathbf{\Theta}}}\right)^{-1} \frac{\partial \widehat{\mathcal{I}}_{\widehat{\mathbf{\Theta}}}}{\partial \mathbf{\Theta}}^{\mathsf{T}} \left(\widehat{\mathcal{I}}_{\widehat{\mathbf{\Theta}}}\right)^{-1} c_{\beta}$$

where  $\Sigma_{\Theta}$  is the variance-covariance matrix of all model coefficients,  $\mathcal{I}_{\Theta}$  the information matrix for all model coefficients,  $c_{\beta}$  a matrix used to select the element relative to  $\beta$  in the first derivative of the information matrix, and  $\frac{\partial}{\partial \Theta}$  denotes the vector of derivatives with respect to all model coefficients.

The derivative of the information matrix (i.e. negative hessian) can then be computed using numerical derivatives or using analytical formula. To simplify the derivation of the formula we will only derive them at the maximum likelihood, i.e. when  $\mathbb{E}\left[\frac{\partial \mathcal{H}(\theta,\theta'|\mathbf{X})}{\partial \theta''}\right] = \frac{\partial \mathbb{E}[\mathcal{H}(\theta,\theta'|\mathbf{X})]}{\partial \theta''}$  where the expectation is taken over  $\mathbf{X}$ . We can therefore take the derivative of formula (B). We first note that its derivative with respect to the mean parameters is 0. So we just need to compute the derivative with respect to a variance parameter  $\theta''$ :

$$\frac{\partial \mathbb{E}\left[\mathcal{H}(\theta, \theta') | \mathbf{X}\right]}{\partial \theta''} + \sum_{i=1}^{n} w_{i} \left(-\frac{1}{2} tr\left(-2\Omega_{i}(\mathbf{\Theta})^{-1} \frac{\partial \Omega_{i}(\mathbf{\Theta})}{\partial \theta''} \Omega_{i}(\mathbf{\Theta})^{-1} \frac{\partial \Omega_{i}(\mathbf{\Theta})}{\partial \theta'} \Omega_{i}(\mathbf{\Theta})^{-1} \frac{\partial \Omega_{i}(\mathbf{\Theta})}{\partial \theta} + \Omega_{i}(\mathbf{\Theta})^{-1} \frac{\partial \Omega_{i}(\mathbf{\Theta})}{\partial \theta'} \Omega_{i}(\mathbf{\Theta})^{-1} \frac{\partial^{2} \Omega_{i}(\mathbf{\Theta})}{\partial \theta \partial \theta''} \right) + \frac{\partial \mu(\mathbf{\Theta}, \mathbf{X}_{i})}{\partial \theta} \Omega_{i}(\mathbf{\Theta})^{-1} \frac{\partial \Omega_{i}(\mathbf{\Theta})}{\partial \theta''} \Omega_{i}(\mathbf{\Theta})^{-1} \frac{\partial \Omega_{i}(\mathbf{\Theta})}{\partial \theta''} \Omega_{i}(\mathbf{\Theta})^{-1} \frac{\partial \mu(\mathbf{\Theta}, \mathbf{X}_{i})}{\partial \theta'}^{\mathsf{T}} \right)$$

# Appendix B Likelihood ratio test with the REML criterion

The blue term of Equation A in the log-likelihood is invariant to re-parameterisation while the red term is not. This means that a re-parametrisation of X into  $\tilde{X} = BX$  with B invertible would not change the likelihood when using ML but would decrease the log-likelihood by  $\log(|B|)$  when using REML.

```
LMMstar.options(optimizer = "FS",
param.optimizer = c(n.iter = 1000, tol.score = 1e-3, tol.param = 1e-5))
```

Let's take an example:

```
## data(gastricbypassL, package = "LMMstar")
dfTest <- gastricbypassL
dfTest$glucagon2 <- dfTest$glucagon*2</pre>
```

where we multiply one column of the design matrix by 2. As mentionned previously this does not affect the log-likelihood when using ML:

```
\label{logLik(lmm(weight $\sim$ glucagon, data = dfTest, structure = UN($\sim$time|id), method = "ML"))} \\ logLik(lmm(weight $\sim$ glucagon2, data = dfTest, structure = UN($\sim$time|id), method = "ML"))} \\
```

```
[1] -245.7909
[1] -245.7909
```

but it does when using REML:

```
\label{logLik(lmm(weight $\sim$ glucagon, data = dfTest, structure = UN($\sim$time|id), method = "REML"))} \\ logLik(lmm(weight $\sim$ glucagon2, data = dfTest, structure = UN($\sim$time|id), method = "REML"))} \\ log(2)
```

```
[1] -245.0382
[1] -245.7313
[1] 0.6931472
```

Therefore, when comparing models with different mean effects there is a risk that the difference (or part of it) in log-likelihood is due to a new parametrisation and no only to a difference in model fit. This would typically be the case when adding an interaction where we can have a smaller restricted log-likehood when considering a more complex model:

```
set.seed(1)
dfTest$ff <- rbinom(NROW(dfTest), size = 1, prob = 0.5)
logLik(lmm(weight ~ glucagon, data = dfTest, structure = UN(~time|id), method = "REML"))
logLik(lmm(weight ~ glucagon*ff, data = dfTest, structure = UN(~time|id), method = "REML"))</pre>
```

```
[1] -245.0382
[1] -245.3555
```

This is quite counter-intuitive as more complex model should lead to better fit and would never happen when using ML:

```
logLik(lmm(weight \sim glucagon, data = dfTest, structure = UN(\sim time|id), method = "ML")) \\ logLik(lmm(weight \sim glucagon*ff, data = dfTest, structure = UN(\sim time|id), method = "ML"))
```

- [1] -245.7909
- [1] -245.3593

This is why, unless one knows what he/she is doing, it is not recommanded to use likelihood ratio test to assess relevance of mean parameters in mixed models estimated with REML.
